# Abstract

In Computer Security one of the most feared threats is a bootkit, executing at the beginning of a computers boot chain, before the operating system and accompanying antivirus programs. With the widespread adaption of standardized UEFI firmware these threats have become less machine dependent and can now target a host of systems at once. Past analyses about bootkits have been case studies of their appearances in the wild, this thesis instead aims to be a more practical approach by developing a bootkit and analyzing the challenges doing so. We restrict our analysis by assuming an attacker has already gained read and write access to the BIOS image and is thus only facing security mechanisms involved during and with execution of the bootkit. Our bootkit was able to achieve elevated execution on Windows 11 by exploiting unrestricted hard drive access to edit Windows Registries, this was also possible on BitLocker encrypted hard drives by keylogging the Recovery Key. UEFI makes it very easy for an attacker who has gained access to the System Firmware to leverage its powers and gain full control over the system.

## Abstract (different language)

Hello, here is some text without a meaning. This text should show what a printed text will look like at this place. If you read this text, you will get no information. Really? Is there no information? Is there a difference between this text and some nonsense like “Huardest gefburn”? Kjift – not at all! A blind text like this gives you information about the selected font, how the letters are written and an impression of the look. This text should contain all letters of the alphabet and it should be written in of the original language. There is no need for special content, but the length of words should match the language.

# Introduction

definition of rootkit/bootkit persistence goals 1/3 - 1/2 pages

# Background

The following introduces the background information necessary to understand the employment of a Unified Extensible Firmware Interface (UEFI) rootkit. This includes the general workings of the Platform Initialization (PI) and UEFI, the UEFI programming model and interface itself; as well as its security mechanisms. It is also necessary to understand our target's defenses, for this, we briefly describe the Windows security mechanisms faced when performing our attacks.

## 2.1 Security Theory

## 2.2 UEFI/PI

“The UEFI specifications define a new model for the interface between personal-computer Operating System (OS) and Platform Firmware (PF). [...] Together, these provide a standard environment for booting an OS and running pre-boot applications” [For].

UEFI is pure interface spec [ZRM17] It was designed to replace the legacy Boot Firmware Basic Input/Output System (BIOS), while also often offering a backwards compatible mode with the Compatibility Support Module (CSM). The specification is a pure interface specification thus merely states what interfaces and structures a PF has to offer and what an OS may use. how it is implemented by PF what is used by OS boot- and runtime service functions for the bootloader and os to call datatables containing platform-related information - complete solution describing all features and capabilities - abstract interfaces to support a range of processors without the need for knowledge about underlying hardware for the bootloader - sharable persistent storage for platform support code security

### 2.2.1 Boot Sequence

focus will be on dxs and transient system load

## 1. Security (SEC)

The SEC phase is the first phase in the UEFI boot process. It is specified in [For20, Vol 1, Section 13 ]. Under its responsibilities fall setting up temporary memory used for the stack and the establishment of the system's root of trust which is a foundation for all secure operations. Inductive security designs rely on this root of trust to build a chain of trust by having a module verify the integrity of its subsequent module.

Part of this process is a so called Hand-off Block (HOB) with a function pointer to a procedure to verify PE modules.

SEC Platform Information PPI information about the health of the processor

SEC HOB Data PPI

## 2. Pre-EFI Initialization (PEI)

- init permanent memory
- describe memory in HOBs
- describe FV! (FV!) in HOBs
- pass control to Driver Execution Environment (DXE)

crisis recovery (what is this?) resuming from S3 sleep state linear array of RAM  
Pre-EFI Initialization Module (PEIM) provides a framework to allow vendors to supply separate initialization modules for each functionally distinct piece of system hardware that must be initialized prior to the DXE phase [For20]

maintenance of chain of trust, protection against unauthorized updates to the PEI phase or modules authentication of the PEI Foundation and its modules provide core PEI module (PEI foundation) processor architecture independent, supports add-in modules from vendors for processors, chipsets, RAM

Locating, validating, and dispatching PEIMs Facilitating communication between PEIMs Providing handoff data to subsequent phases

### 3. Driver Execution Environment (DXE)

dxs core/foundation platform independent is implementation of UEFI UEFI Boot Services UEFI Runtime Services DXE Services

dxs dispatcher discover drivers stored in firmware volumes and execute in proper order apriori file optionally in FV or depex of driver after dispatching all drivers in the dispatch queue hands control over to BDS

dxs drivers init processor, chipset and platform produce architectural protocols and i/o abstractions for consoles and boot devices

initializing the processor, chipset, and platform components providing software abstractions for system services, console devices, and boot devices.

### 4. Boot Device Selection (BDS)

DXE architectural protocol one function entry platform boot

attempts to connect boot devices required to load the os discovers volumes containing new drivers calls DXE dispatcher doesnt return when successfully booting OS

UEFI itself only specifies the NVRAM variables used in selecting boot options leaves the implementation of the menu system as value added implementation space [For21]

[For20]

- Initializing console devices
- Loading device drivers

- Attempting to load and execute boot selections

## 5. Transient System Load (TSL)

boottime and runtime services/driver bootloader ExitBootServices()

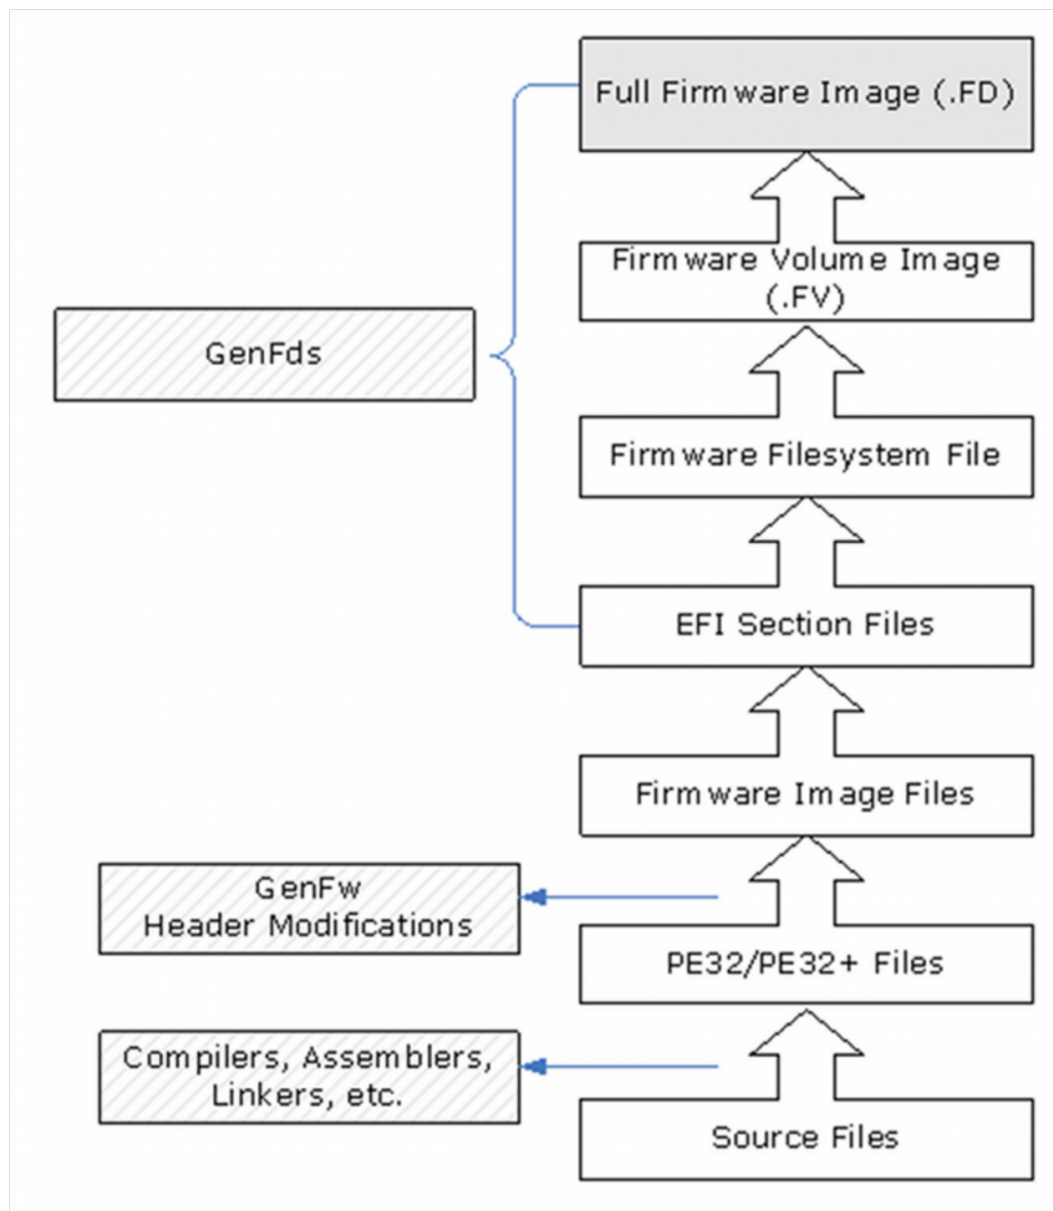

## 6. Runtime (RT)

runtime services/driver

## 7. Afterlife (AL)

hibernation sleep

## 2.2.2 UEFI/PI Firmware Images

firmware device persistent physical device contains firmware code and/or data typically flash may be divided into smaller pieces to form multiple logical firmware devices multiple physical firmware devices may be aggregated into one larger logical firmware device

**FV!** (FV!) logical device organized into a file system attributes such as - size - formatting - read/write access

**FFS!** (FFS!) organization of files and free space no directory hierarchy all files flat in root dir parsing requires walking from beginning to end

firmware files types

some file types are sub-divided in file sections

file sections can be either encapsulation or leaf sections such as PE32 RAW  
VERSION TE

dxs drivers files contain one PE32 executable section may contain version section  
may contain dxs depex section

freeform files can contain any combination of sections

PEI phase Service Table FfsFindNextFile, FfsFindFileByName and FfsGetFileInfo

DXE phase

depex

[Tia]

### 2.2.3 UEFI Images

files containing executable code subset of PE32+ file format with modified header  
signature to distinguish from normal PE32 Images + stands for addition of 64-bit  
relocation fix-up extension

relocatable fixed and dynamic address loading loaded fully into memory and reloac-  
tion fix ups

three different subsystems types: application, boot service driver and runtime service  
driver boot and runtime memory

application vs os loader vs driver memory they reside in unloaded on return unloaded  
on error

memory marked as code and data jump to entry point

what is the boot manager boot manager = bds

#### UEFI Applications

example efi shell loaded by boot manager or other applications return or calling exit  
specifically always unloaded from memory

## UEFI OS Loaders

example windows boot manager normally take over control from the firmware upon load behaves like a normal UEFI application - only use memory allocated from the firmware - only use services/protocols to access devices that the firmware exposes - conform to driver specifications to access hardware on error can return allocated resources with Exit boot service with error specific information given in ExitData on success take full control with ExitBootServices boot service all boot services in the system are terminated, including memory management UEFI OS loader now responsible

## UEFI Drivers

loaded by boot manager, UEFI firmware (DXE foundation), or other applications example payload unloaded only when returning error code persistent on success boot and runtime drivers only difference is that runtime are available after Exit-BootServices was called boottime drivers are terminated and memory is released runtime drivers are fixed up with virtual mappings upon SetVirtualAddressMap call has to convert its allocated memory

### 2.2.4 Firmware Core

system tables offers boot and runtime services supplied by drivers implementing architectural protocols handles

protocols identified with guides

### 2.2.5 edk2

build system

BaseTools package process files compiled by third party tools, as well as text and Unicode files in order to create UEFI or PI compliant binary image files []

### 2.2.6 Security

others not discussed further user identification

## Secure Boot

driver signing executables may be located on un-secured media system provider can authenticate either origin or integrity

digital signature data to sign public/private key pair used to verify integrity

embedded within PE file

calculating the pe image hash - hashing the pe header, omitting the file's checksum and the Certificate Table entry in Optional Header Data Directories - sorting and hashing pe sections omitting attribute certificate table and hash remaining data

[Mic]

guarantees only valid 3rd party firmware code can run in OEM firmware environment  
UEFI Secure Boot assumes the system firmware is a trusted entity any 3rd party firmware code is not trusted including bootloader/osloader, PCI option ROMs, UEFI shell tool

two parts verification of the boot image and verification of updates to the image security database [**understanding-uefi-secure-boot-chain**]

## Signed Capsule Update

DXE SMM Ready to Lock Vol4

Capsule Architectural Protocol

provides CapsuleUpdate() QueryCapsuleCapabilities() of the runtime services table

flash device security

## TPM measurements

SEC starts by measuring PEI

## 2.3 Windows

### 2.3.1 User Access Control (UAC)

### 2.3.2 Signing

### 2.3.3 Bitlocker

# Attacks

Our different attacks face three escalating levels of security mechanisms. The first is with Secure Boot and Bitlocker disabled, the second is just Secure Boot enabled and the third is both Secure Boot and Bitlocker enabled with the focus of the study on Bitlocker. All attacks share the requirement of being able to add DXE Drivers to the DXE Volume. This can be achieved by having read/write access to the SPI flash or using the Signed Capsule Update. Gaining read/write access to the SPI Flash is possible either through physical access to the device by using an SPI clamp on the chip itself or through exploits like for example the . Signed Capsule Updates can be leveraged with access to private vendor information by signing the payload to make it appear legitimate or by intercepting the distribution process and employing infected firmware.

## 4.1 Neither Secure Boot nor Bitlocker

use read access to dump image since it an FV with FFS we can open with UEFITool  
remove previous NTFS driver if present, for full control, might be read only etc in  
UEFITool search and remove add in NTFS driver use write access

try in EFI shell navigate to Windows folder create folder

how does one compile uefi application with edk2 it's open source so we can look up  
examples for most stuff

try in code compile dx driver within ovmf to receive .ffs file with version depex  
user interface section SimpleFileSystem Protocol iteration write failed on hibernated  
file patch to allow write on hibernated drives

pack executable binary as uefi module edk2 produces freeform image with one raw  
section iterate over firmware volume protocols search for payload guid check size  
match override notepad works

but no automatic execution nor elevated privileges dll proxying dll hijacking registry  
editing

Task Scheduler defined in xml cached in registry edit with start cmd.exe and trigger manually whoami

chntpw and reged port to uefi edit Task in machine under Control maybe look if just adding a key would have also worked export target registry key modify so that registry key can differ and found via matching values import and override registry key on target machine payload whoami localsystem

## 4.2 Secure Boot

how does one enable it mostly comes with default keys OEM expectation: not to boot observation: no difference secure boot default policy snippet option roms and bootloader instead relies on Signed Capsule Updates assumes integrity

## 4.3 Secure Boot and Bitlocker

assumptions: secure boot or not bitlocker enabled with TPM auto decryption

observation: boot execution differs from executing rootkit tpm values different bitlocker auto decryption fails recovery key prompt

what is the reaction of the average user (ask admin for recovery password) type in recovery password alternative would be to remove drive and insert into safe device

prompt is done by the OS Loader ergo still during transient system load phase required to use protocol services therefor uses uefi services for IO such as SimpleTextInputEx Protocol go over the two different input protocols find out which one is used

explain more in depth how protocols are returned to the end user one instance per controller/handle

explain basic hooking explain how we retain information of the hook in question map protocol pointer to hook information keylog recovery key key input advancement is weird and makes tracking tricky

alternatively screen shot still need hook to find when enter is pressed explain how screenshotting works some basic compression wait for recovery key send recovery key on enter press

on real hardware network stack wasn't installed onto handles when boot over ip was disabled compared loaded dx drivers between both configurations with efi shell Realtek Family driver not loaded load manually reinstall all handle to controllers to enable network stack regardless

sending key out is only good for physical access attack vector dislocker linux utility mount encrypted drive with decryption mean read and write access dual boot in vm enter password and it works port to uefi bitlocker encrypts block-wise uefi protocol stack hook block io again hook data mapping dislocker validate block solves recovery key advancement issue

hook ExitBootServices enable hook write payload import registry key disable hook

next boot would require to input tpm values again update tpm values in payload caveat pin? look into this

persistence when part of root of trust fresh install / tpm update values hook Trusted Computing Group 2 (TCG2) Protocol TPM communication receive bitlocker vmk key and send to dislocker

## Discussion

attack assumption reflected to real world applicability

social engineering aspekt

driver vorhanden und was mitbringen, debloating

### 5.1 Rootkit classification

statistiken zu bilocker und secureboot auf systemen

industrie standard zur system security in firmen

### 5.2 Mitigations

hardware validated boot

inaccessible spi flash

tpm + pin detectability

googeln wie legitime recovery key prompt reaktion aussieht

enterprise policy recovery key einschraenkbar?

enterprise policy on recovery key loss

### 5.2.1 User awareness

vermitteln was das prompt bedeuten koennte

aber kann man einfach nicht anzeigen lassen

Security Flaw of entering a Recovery Password in an inheritly unsafe System

enterprise doesnt hand out recovery keys and instead receives hard drive

!!!!!!!!!!!!!!!!!!!!!! without hardware chain of trust a compromised system can patch/change any software and fixes are impossible

phishing prompts on their own

# Conclusion

## 6.1 Achieved Goals

when we are already in the image we can gain full control over the system system cant be trusted anymore e.g. uefi services full file access escalate it to local system level execution bitlocker has the flaw of allowing to enter critical information into an inherently untrustable system on the other hand one could force such a prompt themselves mere existence of a recovery key is a security flaw

## 6.2 Future Work

tpm and pin capsule update
